

# Methods

## 1 General formulation

$$\begin{aligned} \min_{x \in \mathbb{R}^n} f(x) \\ \text{s.t. } g_i(x) \leq 0, \quad i = 1, \dots, m \\ h_j(x) = 0, \quad j = 1, \dots, k \end{aligned}$$

Some necessary or/and sufficient conditions are known (See [Optimality conditions. KKT](#) and [Convex optimization problem](#)).

- In fact, there might be very challenging to recognize the convenient form of optimization problem.
- Analytical solution of KKT could be inviable.

### 1.1 Iterative methods

Typically, the methods generate an infinite sequence of approximate solutions

$$\{x_t\},$$

which for a finite number of steps (or better - time) converges to an optimal (at least one of the optimal) solution  $x_*$ .

Illustration of iterative method approaches to the solution  $x^*$

```
def GeneralScheme(x, epsilon):  
    while not StopCriterion(x, epsilon):  
        OracleResponse = RequestOracle(x)  
        x = NextPoint(x, OracleResponse)  
    return x
```

### 1.2 Oracle conception

оракъл  
 $L$   
 $2$   
 $x_k$

$f(x_k)$   
 $f'(x_k)$   
 $f''(x_k)$   
**ORACLE**

$f(x_k), f'(x_k), f''(x_k)$

**Black - box**

Depending on the maximum order of derivative available from the oracle we call the oracles as zero order, first order, second order oracle and etc.

**2 Unsolvability of numerical optimization problem**

$\min_{x \in \mathbb{C}^n} f(x)$

In general, **optimization problems are unsolvable.**

Consider the following simple optimization problem of a function over unit cube:

$$\begin{aligned} \min_{x \in \mathbb{R}^n} f(x) \\ \text{s.t. } x \in \mathbb{C}^n \end{aligned}$$

We assume, that the objective function  $f(\cdot) : \mathbb{R}^n \rightarrow \mathbb{R}$  is Lipschitz continuous on  $\mathbb{C}^n$ :

$$|f(x) - f(y)| \leq L \|x - y\|_\infty \forall x, y \in \mathbb{C}^n,$$

with some constant  $L$  (Lipschitz constant). Here  $\mathbb{C}^n$  - the  $n$ -dimensional unit cube

$$\mathbb{C}^n = \{x \in \mathbb{R}^n \mid 0 \leq x_i \leq 1, i = 1, \dots, n\}$$

Our goal is to find such  $\tilde{x} : |f(\tilde{x}) - f^*| \leq \epsilon$  for some positive  $\epsilon$ . Here  $f^*$  is the global minima of the problem. Uniform grid with  $p$  points on each dimension guarantees at least this quality:

$$\|\tilde{x} - x_*\|_\infty \leq \frac{1}{2p},$$

which means, that

$$|f(\tilde{x}) - f(x_*)| \leq \frac{L}{2p} = \epsilon$$

$$p = \frac{L}{2\epsilon}$$

Our goal is to find the  $p$  for some  $\epsilon$ . So, we need to sample  $(\frac{L}{2\epsilon})^n$  points, since we need to measure function in  $p^n$  points. Doesn't look scary, but if we'll take  $L = 2, n = 11, \epsilon = 0.01$ , computations on the modern personal computers will take 31,250,000 years.

~ 3MILL NET.

**2.1 Stopping rules**

- Argument closeness:

- Function value closeness:

$$\|x_k - x_*\|_2 < \epsilon$$

$$\|f_k - f^*\|_2 < \epsilon$$

$$\|f'(x_k)\|_2 < \epsilon$$

- Closeness to a critical point

But  $x_*$  and  $f^* = f(x_*)$  are unknown!

Sometimes, we can use the trick:

$$\|x_{k+1} - x_k\| = \|x_{k+1} - x_k + x_* - x_*\| \leq \|x_{k+1} - x_*\| + \|x_k - x_*\| \leq 2\epsilon$$

**Note:** it's better to use relative changing of these values, i.e.

$$\frac{\|x_{k+1} - x_k\|_2}{\|x_k\|_2}$$

$\leq \epsilon$        $\leq \epsilon$

### Example

Suppose, you are trying to estimate the vector  $x_{true}$  with some approximation  $x_{approx}$ . One can choose between two relative errors:

$$\frac{\|x_{approx} - x_{true}\|}{\|x_{approx}\|} \quad \frac{\|x_{approx} - x_{true}\|}{\|x_{true}\|}$$

If both  $x_{approx}$  and  $x_{true}$  are close to each other, then the difference between them is small, while if your approximation is far from the truth (say,  $x_{approx} = 10x_{true}$  or  $x_{approx} = 0.01x_{true}$  they differ drastically).

Mirror descent

# Rates of convergence

## 1 Speed of convergence

In order to compare performance of algorithms we need to define a terminology for different types of convergence. Let  $r_k = \{\|x_k - x^*\|_2\}$  be a sequence in  $\mathbb{R}^n$  that converges to zero.

### 1.1 Linear convergence

We can define the *linear* convergence in a two different forms:

$$\|x_{k+1} - x^*\|_2 \leq Cq^k \quad \text{or} \quad \|x_{k+1} - x^*\|_2 \leq q\|x_k - x^*\|_2,$$

for all sufficiently large  $k$ . Here  $q \in (0, 1)$  and  $0 < C < \infty$ . This means that the distance to the solution  $x^*$  decreases at each iteration by at least a constant factor bounded away from 1. Note, that sometimes this type of convergence is also called *exponential* or *geometric*. We call the  $q$  the convergence rate.

$r_{k+1} \leq q \cdot r_k$

#### Question

Suppose, you have two sequences with linear convergence rates  $q_1 = 0.1$  and  $q_2 = 0.7$ , which one is faster?

#### Example

Let us have the following sequence:

$$r_k = \frac{1}{3^k}$$

One can immediately conclude, that we have a linear convergence with parameters  $q = \frac{1}{3}$  and  $C = 1$ .

#### Question

Let us have the following sequence:

$$r_k = \frac{4}{3^k}$$

$q = \frac{1}{3}$   
 $C = 4$

Will this sequence be convergent? What is the convergence rate?

### 1.2 Sublinear convergence

If the sequence  $r_k$  converges to zero, but does not have linear convergence, the convergence is said to be sublinear. Sometimes we can consider the following class of sublinear convergence:

$$\|x_{k+1} - x^*\|_2 \leq Ck^q,$$

where  $q < 0$  and  $0 < C < \infty$ . Note, that sublinear convergence means, that the sequence is converging slower, than any geometric progression.

### 1.3 Superlinear convergence

The convergence is said to be *superlinear* if:

$$\|x_{k+1} - x^*\|_2 \leq Cq^{k^2} \quad \text{or} \quad \|x_{k+1} - x^*\|_2 \leq q_k \|x_k - x^*\|_2,$$

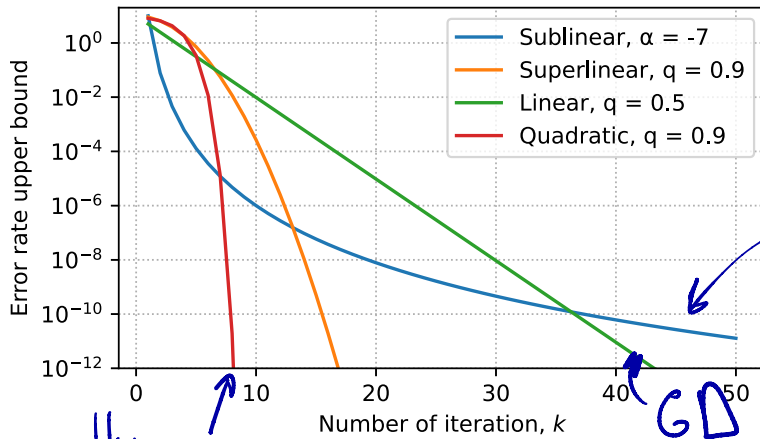

where  $q \in (0, 1)$  or  $0 < C_k < \infty, C_k \rightarrow 0$ . Note, that superlinear convergence is also linear convergence (one can even say, that it is linear convergence with  $q = 0$ ).

$q_k \rightarrow 0$

### 1.4 Quadratic convergence

$$\|x_{k+1} - x^*\|_2 \leq Cq^{2^k} \quad \text{or} \quad \|x_{k+1} - x^*\|_2 \leq C\|x_k - x^*\|_2^2,$$

where  $q \in (0, 1)$  and  $0 < C < \infty$ .

Ньютоны для сильновып. функций  
Difference between the convergence speed

GD для вып. функций

GD для сильновып. функций

Quasi-Newton methods for unconstrained optimization typically converge superlinearly, whereas Newton's method converges quadratically under appropriate assumptions. In contrast, steepest descent algorithms converge only at a linear rate, and when the problem is ill-conditioned the convergence constant  $q$  is close to 1.

## 2 How to determine convergence type

### 2.1 Root test

Let  $\{r_k\}_{k=m}^{\infty}$  be a sequence of non-negative numbers, converging to zero, and let

$$q = \limsup_{k \rightarrow \infty} r_k^{1/k}$$

- if  $0 \leq q < 1$ , then  $\{r_k\}_{k=m}^{\infty}$  has linear convergence with constant  $q$ .
- In particular, if  $q = 0$ , then  $\{r_k\}_{k=m}^{\infty}$  has superlinear convergence.
- If  $q = 1$ , then  $\{r_k\}_{k=m}^{\infty}$  has sublinear convergence.
- The case  $q > 1$  is impossible.

нужен сверху пример  
 $r_k = \frac{1}{k^k} = ?$   
 Тест корнями  
 $\lim_{k \rightarrow \infty} r_k^{1/k} = \left(\frac{1}{k}\right) = \frac{1}{k} = 0$   
 сверхлинейный сходимость

### 2.2 Ratio test

Тест отношениями

Let  $\{r_k\}_{k=m}^{\infty}$  be a sequence of strictly positive numbers converging to zero. Let

$$q = \lim_{k \rightarrow \infty} \frac{r_{k+1}}{r_k}$$

- If there exists  $q$  and  $0 \leq q < 1$ , then  $\{r_k\}_{k=m}^{\infty}$  has linear convergence with constant  $q$ .
- In particular, if  $q = 0$ , then  $\{r_k\}_{k=m}^{\infty}$  has superlinear convergence.
- If  $q$  does not exist, but  $q = \limsup_{k \rightarrow \infty} \frac{r_{k+1}}{r_k} < 1$ , then  $\{r_k\}_{k=m}^{\infty}$  has linear convergence with a constant not exceeding  $q$ .
- If  $\liminf_{k \rightarrow \infty} \frac{r_{k+1}}{r_k} = 1$ , then  $\{r_k\}_{k=m}^{\infty}$  has sublinear convergence.
- The case  $\liminf_{k \rightarrow \infty} \frac{r_{k+1}}{r_k} > 1$  is impossible.
- In all other cases (i.e., when  $\liminf_{k \rightarrow \infty} \frac{r_{k+1}}{r_k} < 1 \leq \limsup_{k \rightarrow \infty} \frac{r_{k+1}}{r_k}$ ) we cannot claim anything concrete about the convergence rate  $\{r_k\}_{k=m}^{\infty}$ .

$r_k = \left(\frac{1}{100500}\right)^k$   
 $r_k^{1/k} = \frac{1}{100500} = q$

на год:

root  
 $\lim_{k \rightarrow \infty} \left(\frac{1}{k}\right)^{\frac{1}{k}} = \lim_{k \rightarrow \infty} \left(\frac{1}{k+1} - 1\right)^{\frac{1}{k}} = \lim_{k \rightarrow \infty} \left(\frac{k+1}{k} - 1\right)^{\frac{1}{k}}$

ratio:  
 $r_{k+1} = \frac{1}{k+1}$   
 $r_k = \frac{1}{k}$

$\frac{r_{k+1}}{r_k} = \frac{k}{k+1} = 1$

сублин.

#### Example

Let us have the following sequence:

Determine the convergence

 **Example**

Let us have the following sequence:

судн.

$$\frac{r_{k+1}}{r_k} = \frac{\frac{k^2}{(k+1)^2}}{\frac{k^2}{(k+1)^2}} = 1$$

$r_k = \frac{1}{k^2}$      $\frac{1}{k^{100500}}$

Determine the convergence

 **Example**

Let us have the following sequence:

$$r_k = \frac{1}{k^q}, q > 1$$

Determine the convergence

 **Try to use root test here**

Let us have the following sequence:

$$r_k = \frac{1}{k^k}$$

Determine the convergence
